

2025

Annual Drinking Water System Report

A.L. Dafoe (Napanee) Drinking Water System

DWS# 220002226

75 East Street
Napanee, Ontario

Prepared: February 2026

Executive Summary

The A.L. Dafoe Water Treatment Plant is a conventional design, chemically assisted filtration plant that treats water drawn from Lake Ontario and supplies drinking water to approximately 8500 residents of the town of Napanee. Reliability of the system is supported by continuous monitoring instrumentation, process alarms, and critical equipment redundancy.

During 2025, the volume of treated water provided to the community increased by approximately 5 percent when compared to that produced during 2024. Average day flow measured in 2025 was approximately 44 percent of the plant design capacity of 10,450 m³/d, while the maximum day flow amounted to approximately 72 percent of that capacity.

Water samples collected throughout the process are tested for over 80 different parameters to evaluate treatment efficiency and to ensure finished water quality. Target parameters range from critical indicators related to potential acute health effects to non-health related parameters that aid in assessing process performance or the aesthetic quality of the drinking water. All test results from samples collected during 2025 met the stringent requirements of the Ontario Drinking Water Quality Standards.

In addition to ongoing routine preventive maintenance practices, notable improvements during 2025 included:

- Replacement of 234 residential water meters to improve the monitoring of water usage and to aid in reducing water loss.
- ROV (Remotely Operated Vehicle) inspections for the treated water storage tank and tower.

The Town of Greater Napanee has successfully implemented a quality management system that continues to conform to the requirements of the Ontario Drinking Water Quality Management Standard. Implementation of the system demonstrates the Town's commitment to continual improvement.

Table 13: Results of samples collected and analyzed to meet the testing requirements under Schedule 15.1 of O. Reg. 170/03	31

Key Words & Terms

m³/d	cubic metres per day (1m ³ = 1000 litres)
mg/L	milligrams per litre, (1 part in 1,000,000)
ug/L	micrograms per litre, (1 part in 1,000,000,000)
ACU	apparent colour units (standard unit to quantify colour in water)
HPC	Heterotrophic Plate Count
NTU	nephelometric turbidity units (standard unit to quantify turbidity in water)
MAC	maximum acceptable concentration
IMAC	interim maximum acceptable concentration
AO	aesthetic objective (non-health related)

Coagulation / Flocculation refers to the water treatment chemical processes that convert small particles of suspended solids into larger, more easily settled clumps.

CT is the product of chlorine residual concentration and the time the residual remains in the water until the first consumer – effective disinfection requires adequate CT

Disinfection refers to the process that kills or inactivates disease-causing organisms in water, usually involving the addition of chlorine.

Escherichia Coli (E. Coli) refers to a subgroup of fecal coliform bacteria that reside in the digestive systems of warm blooded animals. The presence of *E. Coli* in drinking water is a strong indicator of fecal contamination. *E. Coli* is rapidly destroyed by chlorine.

Filter Underdrain is located at filter bottom, the under-drain allows the passage of filtered water while retaining filter media

Flocculation Tank is a large baffled process tank that gently mixes the process flow to increase the size of floc formed by coagulant

Heterotrophic Plate Count (HPC) is a microbial test method that quantifies levels of heterotrophic bacteria. Most bacteria, including many of those common in drinking water systems, are heterotrophs. Within a distribution system, increases in the density of HPC bacteria are usually the result of bacterial re-growth which is influenced by the quality of the water entering the system, temperature, flow conditions (i.e. stagnation), presence of a disinfectant residual, construction materials, and the availability of nutrients for growth. HPC in drinking water are not considered a direct health threat to the general public.

Inorganic refers to non-carbon based substances. Common inorganic substances in water include metals, minerals, nutrients, and salts.

ODWQS – refers to the Ontario Drinking Water Quality Standards. The ODWQS define the quality standards, objectives, and guidelines to be followed for the protection of public health through the provision of safe and aesthetically acceptable drinking water supply.

Ontario Regulation 170/03 or O.Reg.170/03 - refers to the Drinking Water Systems Regulation as amended.

Ontario Regulation 169/03 or O.Reg.169/03 - refers to the ODWQS Regulation as amended.

Organic refers to a large group of carbon-based chemical compounds including all animal and vegetable matter plus many synthetic compounds such as pesticides and industrial solvents.

Raw Water is defined as surface (lakes, rivers) or ground water (wells) available as a source of drinking water that has not received any treatment.

Sedimentation refers to the water treatment process where the velocity of water is reduced in large tanks so that the suspended material can settle by gravity.

Static Mixer is a helical shaped pipe insert designed to create an extremely turbulent flow pattern

Total Coliform Bacteria are a group of commonly occurring, mostly harmless bacteria that live in soil and water as well as the gut of animals. Their presence in a water sample may be indicative of inadequate filtration and/or inadequate disinfection.

Turbidity refers to a physical characteristic of water that causes a cloudy appearance. Turbidity is caused by the presence of suspended matter. The substances that cause turbidity can shield potentially pathogenic organisms from disinfection.

Waste Equalization Tank refers to a large holding tank used for temporary storage and mixing of batch waste stream discharges

Introduction

The 2025 Annual Drinking Water Report for the A.L. Dafoe (Napanee) Drinking Water System summarizes plant operations and treated water quality with reference to the requirements of:

- Ontario Regulation 170/03 (O. Reg. 170/03)
- Ontario Regulation 169/03 (O. Reg. 169/03)
- Permit to Take Water 0846-D9QN82
- Municipal Drinking Water Licence 157-101
- Drinking Water Works Permit 157-201

This report consolidates the reporting requirements specified as “Annual Report” in O.Reg.170/03, Section 11, and “Summary Report” in O.Reg.170/03, Schedule 22.

Information provided in this report includes the following:

- Section 1 of the report provides a detailed description of the water treatment process.
- Section 2 provides a summary of reports to the Ministry under Subsection 17(1) of the Safe Drinking Water Act (notices of adverse water quality) and Schedule 16, Section 16-4 of O. Reg. 170/03 (notice of inadequate disinfection), as well as any corrective actions taken under Schedule 17.
- Section 3 summarizes the analytical data generated from “in house” analysis as well as contracted analyses conducted at an accredited laboratory in accordance with O.Reg.170/03. Raw and treated water flow rates are also discussed in Section 3. Chemicals used in the treatment process are discussed in both Sections 1 and 3 and are summarized in the tables appearing at the end of this report.

-
- Section 4 contains a summary of significant maintenance and upgrading projects completed during 2025.

Copies of Annual Drinking Water Reports are available to the public, free of charge, from the Administration Office located at 99-A Advance Avenue in Napanee. Reports are also available online at: <http://www.greaternapanee.com>. Additional information on drinking water standards in Ontario is available from the Ontario Ministry of the Environment, Conservation and Parks (<https://www.ontario.ca>).

1 Description of the Treatment Process

Raw Water Supply

Two pumps located at the Lake Ontario Pumping Station (County Road 21 and Highway 33), referred to as low lift pumps, are used to transfer raw water from Lake Ontario to the A.L. Dafoe Water Treatment Plant. Only one pump operates at any given time, while the second is reserved for backup duty. The low lift pumps draw directly from a screened intake crib (to prevent passage of large debris) located 50 meters offshore. The low lift pumps discharge through approximately 16 km of 500 mm diameter pipeline to the reservoirs located at the corner of Golf Course Lane and County Road 8. In the event of a power interruption, the Lake Ontario Pumping Station is equipped with switching gear that accommodates direct connection to a mobile diesel generator.

Raw water flows by gravity through a 400 mm diameter pipe from the reservoirs to the treatment plant. The flow of raw water from the reservoirs is controlled by the volume of treated water stored at the plant. As water is used by the community, valves open to allow raw water into the process to replenish the treated water reserves.

If circumstances arise that prevent the transfer of raw water from Lake Ontario, the treatment plant inlet valves can be manually adjusted to draw from the Napane River.

Pre-chlorination / Zebra Mussel Control

The addition of chlorine to the raw water supply is called pre-chlorination, and serves three main purposes:

1. prevent biological growth within the raw water pipeline and reservoirs
2. provide initial disinfection
3. control the growth of Zebra Mussels

The growth of Zebra Mussels (an invasive species in the Great Lakes), if not controlled, can accumulate and eventually plug the raw water intake pipe. Chlorine is added to the

raw water through a diffuser located within the raw water intake crib to control growth in the immediate area of the intake pipe. Chlorine pumping is activated only when the low lift pumps are running to avoid excessive accumulation of chlorine concentration in the aquatic environment surrounding the intake crib. The intake crib was last inspected and cleaned by an underwater inspection contractor in April 2024.

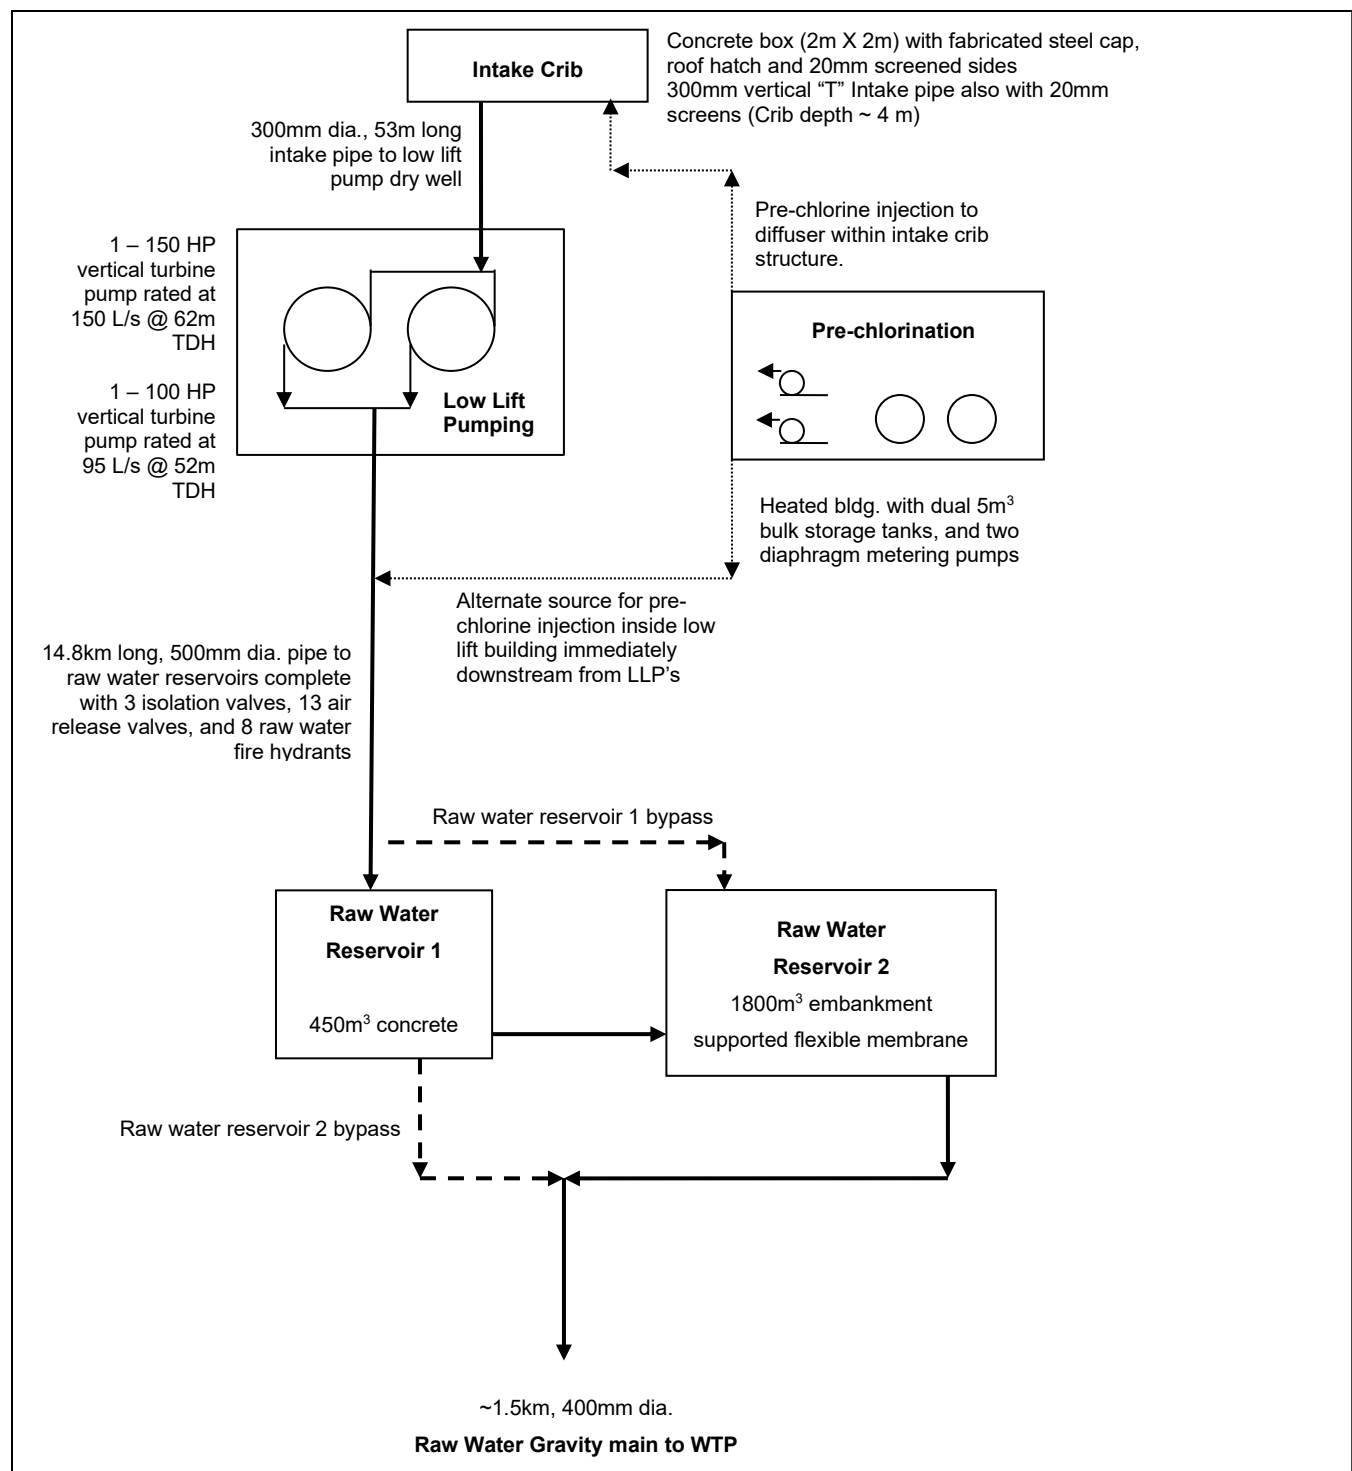

Figure 1: A.L. Dafoe Water Treatment Plant Raw Water Transmission Schematic

Coagulation / Flocculation / Sedimentation

Aluminum sulfate (liquid alum), which acts as a coagulant, is added to the incoming raw water upstream from the flocculation tank. The coagulant converts dispersed and colloidal solids suspended in the raw water (measured as turbidity) to small visible clumps. The coagulation reactions occur very rapidly as the alum and process water mix together within a static mixer. As the coagulated process water passes through the baffled flocculation tank, the coagulated clumps collide, forming larger clumps commonly referred to as floc.

Following the flocculation tank, the process water flows into large rectangular sedimentation tanks where velocity is decreased allowing the relatively heavy floc particles to settle by gravity. Accumulated floc (alum sludge) from the bottom of the sedimentation tanks is discharged to the waste residuals treatment process (described in more detail below). The upper, clear portion of the sedimentation tank flows to the filters for further treatment.

Coagulation, flocculation and sedimentation are treatment processes which together serve as a barrier to the passage of potentially harmful organisms by removing turbidity from the water.

Filtration

Overflow from the sedimentation tanks flows to the top of the filters. Flow moves downward through two parallel dual media filters comprised of a top layer of granular activated carbon (GAC) overlying a lower layer of sand.

The GAC layer adsorbs compounds that cause taste and odour as well as other trace organic compounds sometimes present in the raw water supply. GAC is effective in removing algal toxins such as those produced by blue-green algae.

Filtration, which takes place in the sand layer, physically removes suspended particles, including floc which may carry over from the sedimentation tanks. The filtered water passes through the filter under-drain and into storage reservoirs, commonly referred to

as clearwells.

Debris which accumulates on the filter media must be periodically removed by a procedure called backwashing. During backwashing, the filter is isolated from the process and treated water is pumped upward, (reversed from normal filter flow), expanding the media bed and loosening accumulated debris. The backwash water with loosened debris is discharged to the waste residuals treatment process.

Disinfection (Chlorination)

Chlorine, in the form of liquid sodium hypochlorite, is added to the process in two locations. Raw water is chlorinated to control the growth of Zebra Mussels and to limit biological growth in the raw water pipeline and reservoir.

The second point of chlorine addition, referred to as post-chlorination, occurs immediately upstream from the treated water clearwells. Post-chlorination serves as the final barrier ensuring that potentially harmful organisms do not enter the town distribution system. A sufficient dosage of chlorine is added at the purification plant to achieve the required disinfection CT and to maintain a residual concentration throughout the distribution system. Distribution chlorine residual prevents biological growth within the distribution piping.

Treated Water Storage Tanks and Pressure Booster Stations

Treated water is pumped from the treated water clearwells into the distribution system. Constant pressure is maintained in the central area of the distribution system by the water column height in the two treated water storage tanks, both integral components of the distribution system. The storage tank is located on County Road 2 and provides 4600 m³ of treated water storage capacity, while the older elevated storage tower on East Street provides approximately 1100 m³ of treated water storage capacity for use during periods of high demand and for community fire protection.

The distribution system also includes two pressure booster stations. The booster stations house inline pumps that restore adequate water pressure to areas distant or

elevated in relation to the treatment plant or storage tanks. One station is located on McCabe Street to overcome the head-loss caused by the relatively higher elevation at the southern extreme of the distribution system. The second station is located on Community Road and maintains pressure to the industrial area north of Highway 401.

Treatment Chemicals

Two chemicals, sodium hypochlorite and aluminum sulfate, are used in the A. L. Dafoe Water Treatment Plant process.

Sodium hypochlorite is added for pre-chlorination and Zebra Mussel control at the Lake Ontario Pumping Station, and for post-chlorination disinfection at the treatment plant. The sodium hypochlorite solution contains approximately 12 percent chlorine and meets the standards of the Canadian General Standards Board and American Water Works Association (AWWA) B300-24 for use in drinking water.

Aluminum sulfate, also known as liquid alum, serves as a coagulant in the treatment process. (Refer to subsection describing coagulation / sedimentation.) The liquid alum meets all specifications for AWWA B403-24 and the National Sanitation Foundation Standard 60 for potable water use at a maximum dosage of 150 mg/L.

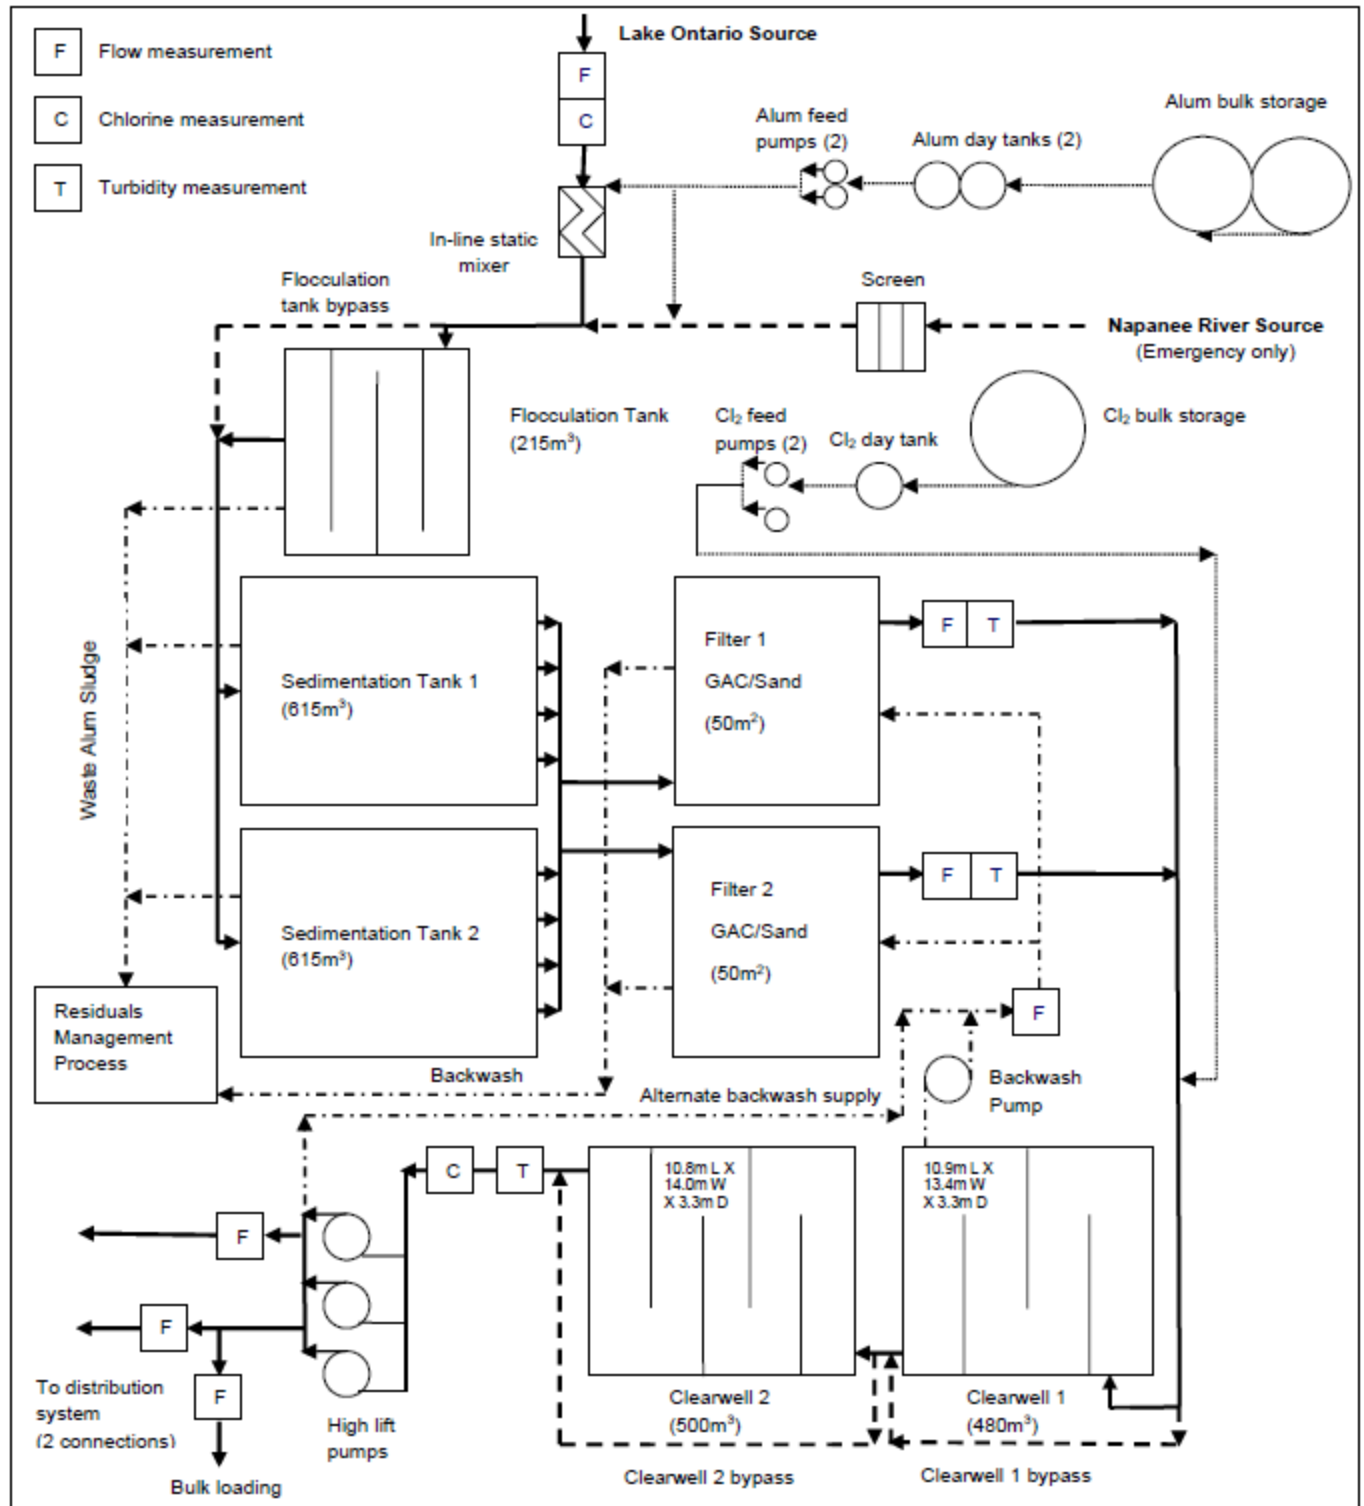

Figure 2: A.L. Dafoe Water Treatment Plant Process Schematic

Waste Residuals Treatment

Waste residuals generated through the treatment process include filter backwash water, sedimentation tank sludge, and other wastes discharged during tank maintenance.

Those waste streams are directed to the waste equalization tank. When in operation, the blended waste from the equalization tank is pumped to the waste residuals treatment process described below. A process flow diagram is provided on the following page.

The waste stream enters the residuals treatment process into a draft tube. The draft tube is a vertical cylindrical chamber equipped with a rotating turbine. Polymer is added to the process as a coagulant aid to produce sticky floc particles that clump together particulate matter present in the waste. Floc formation is enhanced by the mixing and shearing action of the turbine. The process stream (with floc particles) is drawn upward by the turbine, over the top edge of the draft tube. Flow then moves at a decreased velocity under one baffle and over a second baffle. The gentle mixing created by the baffles causes the relatively small floc particles to gather, (becoming larger and heavier), prior to entering the settling compartment.

The top portion of the settling compartment contains inclined settling tubes designed to maximize the settling velocity of the floc as flow passes through. The floc settles to the bottom of the settling compartment, while the clear liquid at the top of the settling zone is discharged to the Napanee River. Prior to discharge, the liquid is measured for chlorine residual and suspended solids, and if required, it is dechlorinated before it is released to the Napanee River. Recirculation of settled floc from the bottom of the settling compartment back to the draft tube enhances floc formation in the incoming wastewater at the beginning of the process. Excess accumulation of settled floc is pumped to the sanitary sewer for further treatment at the Napanee Water Pollution Control Plant.

When the waste residuals treatment is not in operation, the blended waste from the

equalization tank is directed directly to the sanitary sewers for treatment at the Napanee Water Pollution Control Plant. In 2025, the blended waste residuals were directed directly to the sanitary sewers for further treatment.

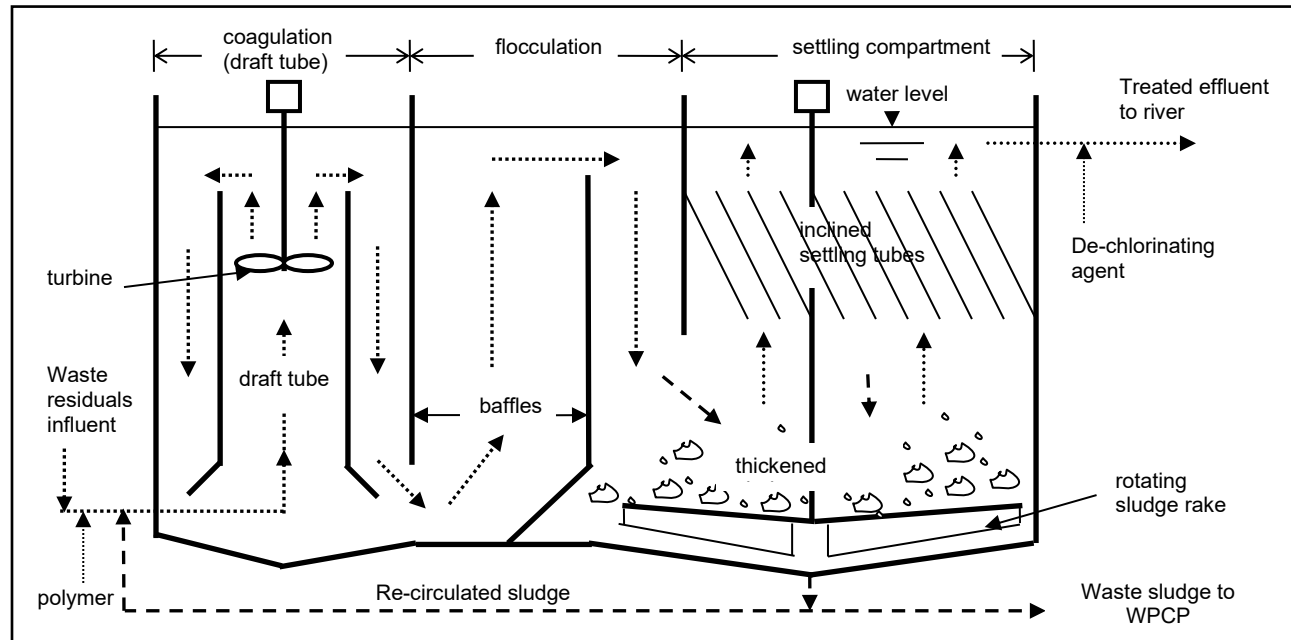

Figure 3: A.L. Dafoe Water Treatment Plant Waste Residuals Treatment Process Schematic

Origins and Types of Contaminants

As water travels over the surface of the land or through the ground, it dissolves naturally occurring minerals and can pick up foreign substances resulting from the animals or from human activity.

The types of contaminants that may be present in source water include:

- Microbiological contaminants, such as pathogens, may come from septic systems, livestock, sewage treatment plants and/or wildlife. Microbiological quality is the most important component of drinking water quality because of its ability to cause acute illness in consumers.

- Inorganic contaminants, such as salts and metals, which can be naturally occurring or result from storm water runoff, industrial or domestic wastewater discharges, oil and gas production, mining, or farming.
- Organic contaminants can be naturally occurring, but most organic compounds of concern are man-made. Pesticides and herbicides are included in this group and may originate from a variety of sources such as agriculture, urban storm water runoff, and/or septic systems.

Multiple Barriers to Microbiological Pathogens

Potentially pathogenic (disease causing) organisms are removed from the raw water source by the following processes:

- pre-chlorination
- coagulation / flocculation / sedimentation
- filtration
- post-chlorination
- distribution system chlorine residual

Laboratory Testing

Ontario Regulation 170/03 and the Municipal Drinking Water License issued for the drinking water facility, dictate the sampling and monitoring requirements for the Napane Drinking Water System. Water quality is tested routinely throughout the treatment process and at the extremities of the distribution system. Testing for any parameters listed as Schedules 1, 2, and 3 of Ontario Regulation 169/03 are conducted at a certified contract laboratory as required by legislation. Certified laboratories must report all drinking water test results directly to the Ministry of the Environment, Conservation and Parks and to the Town of Greater Napane, Growth and Infrastructure Services Department.

Alarms and Staffing

The A.L. Dafoe Water Treatment Plant is typically staffed 8 hours per day, 5 days per week. On weekends and holidays, staff visit the facility to conduct routine rounds and testing. During off-hours, process irregularities or building security breaches are detected by the plant alarm system and relayed to an on-call operator.

2 Reporting of Adverse Water and Other Deficiencies

There were no incidents of adverse water quality in the A.L. Dafoe (Napane) Drinking Water System observed or reported during 2025. There was one (1) incident in December 2025, during which an external contractor drilled through a watermain. At the time, the extent of the damage was unknown, therefore a notice was made to the Medical Officer of Health through the local health unit and the Spills Action Centre. As a result, we were advised to issue a “Precautionary Drinking Water Notice”, in which residents were advised to not drink the water if they noticed any low pressure, unusual odours, or discolouration. A precautionary distribution water sample was collected following repairs, which met the Ontario Drinking Water Quality Standards. The break was categorized as a Class 1 break, and no contamination was suspected.

All samples collected and tested in accordance with O.Reg.170/03 met the requirements of the Ontario Drinking Water Quality Standards. Disinfection of treated water was maintained consistently as prescribed in the MECP publication, *Procedure for Disinfecting Drinking Water in Ontario*. No corrective actions, as detailed in O.Reg.170/03, Schedule 17, were required.

Water quality data and disinfectant residuals are provided in summary tables throughout Section 3 of this report.

3. Flow Measurement and Analytical Testing

Raw and Treated Water Flow

Water supply to the Napanee Distribution System originates from either Lake Ontario or the Napanee River. Lake Ontario is the primary source while the alternate source (Napanee River) is reserved for emergency circumstances if transmission from the Lake were interrupted for an extended period. Permission to draw raw water from those sources is authorized by a Permit to Take Water issued by the Ministry of the Environment, Conservation and Parks. The current permit is valid until October 2034 and allows a maximum taking of 12,000 m³/d. The Permit to Take Water was not exceeded on any day in 2025. Flow meter accuracy is checked and verified annually by a certified technician.

Raw and treated water data collected during 2025 are presented in Table 1. During 2025, all raw water treated at the A.L. Dafoe Water Treatment Plant was pumped from the Lake Ontario source. The average and maximum day raw water flows were 4,414 m³/d and 7,510 m³/d respectively.

Table 1: Summary of raw and treated water flow for 2025

Month	Raw Water Flow (m ³ /day)				Total Raw Water Flow (m ³)	Treated Water Flow (m ³ /day)				Total Treated Water Flow (m ³)
	Min	Max	Max Inst.	Avg.		Min	Max	Max Inst.	Avg.	
January	3264	4565	7.2	3855	119415	3080	4793	7848	3904	121213

July	4412	6539	7.2	5218	161160	4068	6495	8520	5500	170457
August	4363	6749	7.2	5328	165228	4381	7159	7464	5659	175031
September	3893	6226	7.2	4809	144497	4136	7510	8640	5121	153951
October	2702	5807	7.2	4222	130968	3395	5600	9216	4406	136919
November	3351	5229	7.2	3903	117175	3663	4806	7944	4150	124047
December	2963	6021	7.2	3935	122095	2999	6847	9600	4211	130150
Annual	2702	7290	7.2	4414	1611363	2999	7510	9600	4552	1663169
Limits		12000	10	Permit to Take Water			10450	Drinking Water License		

Note: The raw water max instant flow is limited by the filter effluent valves which are programmed to permit a max flow of 7.2 m³/min.

Treated water pumped from the A.L. Dafoe Water Treatment Plant to the Napanee community during 2025 averaged at 4,552 m³/d, which is approximately five (5) percent more than the average day flow recorded for the previous year. Based on the 2025 average day flow, the plant is operating at approximately 44 percent of the design capacity. The maximum day flow recorded in September 2025 represents approximately 72 percent of the design capacity of 10,450 m³/d.

Trending of monthly average day treated water flows comparing data from 2024 and 2025 (Figure 4) indicates that water consumption has remained relatively stable between 2024 and 2025. Consumption appeared to be higher in summer months compared to 2024, likely attributed to a seasonally dry summer in 2025 and increased reliance on Town water.

Figure 4: Monthly average daily treated water flow trends for 2024 and 2025.

Turbidity

Turbidity, a measure of the cloudiness of water due to suspended materials, is monitored daily in the raw water entering the plant and continuously in the effluent from each of the two water treatment plant filters. Measurement of raw water turbidity is necessary to monitor any changes to the raw water that may require adjustment of the treatment process. Filtered water is monitored to verify the particulate removal efficiency of the chemically assisted filtration process.

The maximum acceptable filter effluent turbidity, according to the Ontario Drinking

Water Quality Standards (ODWQS), is 1 NTU. The treatment facility is equipped with process alarms that alert staff to abnormally high turbidity measurements well in advance of reaching that limit. In the event that the alarm set point is exceeded, the filter valves automatically close, halting the production of substandard water until the problem is addressed by operations staff.

Table 2: Summary of turbidity in raw water and filter effluent for 2025

Month	Raw Water Turbidity (NTU)			Filter #1 Effluent Turbidity (NTU)			Filter #2 Effluent Turbidity (NTU)		
	Min.	Max.	Avg.	Min.	Max.	Avg.	Min.	Max.	Avg.
January	0.61	7.60	1.52	0.012	0.240	0.017	0.009	0.100	0.016

May	0.62	2.13	1.13	0.015	0.151	0.023	0.013	0.160	0.022
June	0.46	2.41	1.13	0.014	0.110	0.020	0.011	0.078	0.018
July	0.66	2.43	1.05	0.010	0.194	0.020	0.009	0.306	0.017
August	0.70	8.51	2.02	0.014	0.121	0.019	0.008	0.143	0.015
September	0.64	6.54	1.70	0.008	0.149	0.017	0.007	0.080	0.014
October	0.77	3.57	1.60	0.013	0.110	0.017	0.006	0.077	0.013
November	0.39	4.03	1.12	0.013	0.133	0.016	0.007	0.079	0.014
December	0.82	13.30	3.30	0.013	0.122	0.017	0.007	0.089	0.013
Annual	0.39	13.30	1.55	0.007	0.240	0.019	0.006	0.306	0.017
ODWQS	-	-	-	-	1.0	-	-	1.0	-

Notes: ODWQS refers to the Ontario Drinking Water Quality Standards maximum acceptable concentration.

Raw water turbidity values indicate a source water of generally good clarity, averaging 1.55 NTU and ranging from 0.39 NTU to 13.30 NTU. The annual average filtered water turbidity measured at Filters 1 and 2 were 0.019 NTU and 0.017 NTU respectively, indicating excellent treatment process performance. Filtered water turbidity did not exceed the drinking water standard at any time during 2025. Operation of the continuous turbidity analyzers is checked by conducting periodic duplicate analysis using portable bench top instrumentation. All turbidity monitoring equipment is routinely inspected and calibrated by staff.

Temperature, Colour, pH, and Alkalinity

Temperature, colour, pH, and alkalinity are measured in raw and treated water each weekday and are summarized for 2025 in Table 3.

Table 3: Summary of temperature, pH, alkalinity and colour in raw and treated water for 2025

Month	Raw Water				Treated Water			
	Average Temp. (°C)	Average pH	Average Alkalinity (mg CaCO ₃ /L)	Average Colour (ACU)	Average Temp. (°C)	Average pH	Average Alkalinity (mg CaCO ₃ /L)	Average Colour (ACU)
January	4.1	7.9	87	9	6.9	7.0	79	0
February	2.2	8.0	87	5	4.6	7.1	81	0
March	2.7	8.0	90	9	5.6	7.1	79	0

The data shows that the raw water supply varies significantly in temperature over the course of the year. Raw water temperature ranged from 2.2°C to 21.1°C, while treated water ranged from 4.6°C to 26.1°C. Coagulants (such as alum, which is used in the A.L. Dafoe treatment process) do not act as quickly in colder water and therefore dosage adjustments may be required during winter months.

Colour develops in raw water sources from the decay of naturally occurring organic matter. The resulting colloidal and dissolved organic compounds react with coagulant chemicals and can increase dosage requirements. Colour removal is sometimes enhanced by pre-chlorination. During 2025, raw water colour measurement ranged from 0 apparent colour units (ACU) to 75 ACU, averaging 10 ACU. Effective removal was achieved through the process as the maximum colour in treated water samples in 2025 was 4 ACU.

Coagulants are most effective within specific ranges of pH as alum performs best between pH 5.8 and pH 8.5. It is important to note that alum is an acidic solution which

tends to lower the alkalinity and pH of process water. Both raw and treated water pH values were relatively stable throughout the year, averaging 8.1 and 7.1, respectively.

Closely related to pH, alkalinity is a measurement of the acid buffering capacity of water. (The higher the alkalinity, the more acid that can be added before a change in pH occurs.) Several substances naturally present in raw water are measured as alkalinity, the majority of which are carbonate compounds. Coagulants, when added to water, combine with the alkalinity to produce insoluble metal hydroxides that play an important role in forming good floc. Alum, as mentioned above, is acidic and therefore decreases alkalinity. If too much natural alkalinity is consumed neutralizing the alum, there may be insufficient alkalinity remaining for optimal floc formation. Therefore, if a noticeable drop in pH (and alkalinity) is occurring, it may be necessary to lower the coagulant dosage to conserve alkalinity, or to add alkalinity to the incoming raw water. Raw and treated water alkalinities were relatively consistent through 2025 averaging 92 mg/L and 84 mg/L, respectively. All treated water alkalinity measurements were within the ODWQS recommended operational objective range of 30 – 500 mg/L.

Disinfection

Disinfection of the water supply protects public health by ensuring the inactivation of potentially harmful micro-organisms that may have passed through the treatment process or entered the distribution system by other means. A minimum free chlorine residual of 0.2 mg/L, maintained throughout the distribution system, is recommended by the *Procedure for Disinfecting Drinking Water in Ontario*. Less than 0.05 mg/L free chlorine residual is considered adverse and may pose a potential threat to public health. Additionally, the guideline requires that treated water must be mixed with the disinfectant and retained for a minimum period of time before distributing to customers. This is referred to as CT which is the product of the disinfectant concentration and the amount of time the water is exposed to the disinfectant. Research has demonstrated that CT is directly related to the rate of pathogen inactivation.

Chlorine residuals are monitored continuously in raw and treated water. The treated

water residual analyzer is equipped with alarms that alert the operators to process abnormalities and will shut down the process to prevent improperly disinfected water from entering the distribution system.

Treated water free chlorine residual measured at the treatment facility averaged 1.82 mg/L in 2025, which is well above the guideline minimum value of 0.2 mg/L. It is important to note that chlorine residual typically declines in proportion to the distance from the point of application. Relatively high chlorine residuals are required leaving the plant in order to ensure that at least 0.2 mg/L is maintained throughout the distribution system. Disinfectant residuals are summarized in Tables 4, 5, and 6.

Chlorine residual measurements are conducted using portable bench top instrumentation on distribution system samples and periodically on plant treated water to provide verification of the continuous analyzer values. Calibrations of measurement instruments are routinely conducted by staff.

Bacteriological Testing

Bacteriological testing verifies the effectiveness of the disinfection process by monitoring the presence of indicator organisms in the water supply. The indicator tests include total coliforms (TC), *Escherichia coliforms* (*E. coli*), and heterotrophic plate count (HPC). The confirmed presence of any TC or *E. coli* in the water supply indicates insufficient disinfection and an increased risk to public health.

Bacteriological testing is conducted on samples collected each week from the raw water source, the treatment plant, and at several remote locations within the distribution system. A total of 52 raw water samples were taken from Lake Ontario for bacteriological testing in 2025. A total of 361 water samples were collected from the treatment plant and distribution system for bacteriological testing in 2025. All test results met the requirements of the Ontario Drinking Water Quality Standards. Tables 4, 5 and 6 summarize results of raw, treated and distribution system bacteriological testing.

Table 4: Summary of treated water disinfection and bacteriological results from 2025

Process Chemical Addition

Two chemicals, aluminum sulphate (alum) and sodium hypochlorite are essential additives to the A.L. Dafoe water treatment process. Alum is a commonly used water treatment coagulant that is necessary for the effective operation of the flocculation and sedimentation processes. Average monthly alum dosages at the A. L. Dafoe Water Treatment Plant remained consistent throughout 2025, ranging from a low of 33.6 mg/L to a maximum of 36.0 mg/L.

Aluminum, a component of alum, is sometimes observed in elevated concentrations in treated water when high dosages of alum are applied. Although not identified in the ODWQS as a health risk, high aluminum residual in the distribution system may cause scaling on pipes, interfere with certain industrial processes, or form floc particles within the distribution system. The aluminum concentration was tested in samples of treated water on 249 days in 2025. All results were below the ODWQS operational guideline

limit of 0.1 mg/L. The maximum aluminum concentration observed during 2025 was 0.070 mg/L while the average was 0.020 mg/L.

Sodium hypochlorite is added as a disinfectant to ensure that the treated water is free of active pathogens. Variations in chlorine dosages are typical throughout any given year. Dosage adjustments are made necessary by changes in water temperature, pH, flow rates, and distribution system residuals. Overall chlorine consumption is typically higher during summer months due to the seasonal increase in water demand.

Table 7: Summary of process chemical usage and dosage for 2025

Chemical Testing

Analyses of nearly 70 additional organic and inorganic parameters in the treated water are required at various frequencies. The majority of those substances, listed as Schedules 23 and 24 in Ontario Regulation 170/03 must be tested at least annually. Testing for nitrite, nitrate, trihalomethane, and haloacetic acid compounds is required quarterly, while sodium and fluoride must be tested once every 5 years.

The results of those analyses are summarized in Tables 8, 9, 10, 11 and 12.

Concentrations of the majority of the substances were lower than the analytical method detection limits (either non-existent or in trace levels too low to quantify), while the remaining substances measured below the ODWQS limits.

Table 8: Results of samples collected on January 7, 2025 to meet testing requirements for parameters listed in Schedule 23 of O. Reg. 170/03

Lead Testing

The A.L. Dafoe (Napanee) Drinking Water System qualified for reduced sampling requirements, as measured lead concentrations observed in samples collected from residential plumbing do not pose a risk to public health based on current standards. In 2024, the municipal lead sampling program continued with distribution system testing conducted on January 9, 2024 and July 9, 2024. During each round, staff were required to sample three (3) distribution system locations. All of the required samples were collected, and all were below the Ontario Drinking Water Quality Standards limit for lead. Lead concentrations observed in all of the samples collected were well below the regulatory limit. Napanee continues to be exempt from any further residential plumbing sampling unless future distribution testing indicates a change in water chemistry or elevated lead concentrations. The lead sampling program will continue again in 2027.

Table 13: Results of samples collected and analyzed to meet the testing requirements under Schedule 15.1 of O. Reg. 170/03

Sample Location	09-Jan-24			09-Jul-24		
	Lead (mg/L)	Alkalinity (mg/L)	pH	Lead (mg/L)	Alkalinity (mg/L)	pH
Sample Hydrant: Hwy 2 W	0.00010	86	6.86	0.00013	104	7.32

Sample Hydrant: Palace Rd	0.00014	82	6.77	0.00019	91	7.12
ODWQS Limit / Objective	0.001*	30 - 500	6.5 - 8.5	0.001*	30 - 500	6.5 - 8.5

*Indicates objective for reduced sampling

Waste Residuals Treatment Process

The waste residuals treatment process is designed to thicken the waste generated from the water treatment process which includes alum sludge from the sedimentation process as well as filter backwash water. The thickened waste is discharged to the municipal sewer for further treatment at the Water Pollution Control Plant, while the treated supernatant (effluent) from the process flows to the Napanee River.

Suspended solids were not measured in the effluent from the process, as the residuals treatment process was out of service for 2025, and during that time all process waste was discharged to the sanitary sewer for further treatment.

If effluent is discharged to the Napanee River, composite sampling of the effluent is required once per week. The process is also equipped with continuous suspended solids monitoring instrumentation which will automatically shut down the process if the effluent limit is approached. This safeguard protects the Napanee River from accidental discharges of non-compliant effluent. Effluent from the process is de-chlorinated if necessary, by the addition of sodium bisulphite.

4 System Maintenance and Improvements

Maintenance and improvements at the Napanee facilities during 2025 included the following:

- Distribution system fire hydrants were inspected, lubricated, and flow tested. The hydrant program serves as a preventive maintenance measure that identifies repair requirements and ensures reliability for community fire protection. Flushing also rids the distribution piping of accumulated sediments.
- The Town of Greater Napanee continued to work closely with Quinte Conservation and Cataraqui Region Conservation Authority regarding the approved Source Water Protection Plans and Education and Outreach programs.
- Distribution repair work along County Road 41, south of Hwy 401, which included the removal of a leaking valve.
- 234 residential water meters were replaced within the distribution system as part of the 20-year replacement program. This program enhances accuracy in water usage monitoring and aids in eliminating water loss within the distribution system.
- The SCADA infrastructure at the booster stations were upgraded.
- One chemical chlorine pump was purchased for replacement at the Lake Station.
- ROV inspections at the treated water storage tank and tower.
